

Compiling PDDL3 Qualitative Preferences without Using Automata

...

Abstract

We address the problem of planning with preferences in propositional domains extended with the class of (preferred) temporally extended goals supported in PDDL3, that is part of the standard planning language PDDL since the 5th International Planning Competition (IPC5). Such preferences are useful to characterise plan quality by allowing the user to express certain soft constraints on the state trajectory of the desired solution plans. Starting from the work of Keyder and Geffner on compiling (reachability) soft goals, we propose a compilation scheme for translating a STRIPS problem enriched with qualitative PDDL3 preferences (and possibly also with soft goals) into an equivalent STRIPS problem with action costs. The proposed compilation, which supports all types of preferences in the benchmarks from IPC5, allows many existing STRIPS planners to immediately address planning with preferences. An experimental analysis presented in the paper evaluates the performance of state-of-the-art STRIPS planners supporting action costs using our compilation approach to deal with qualitative PDDL3 preferences. The results indicate that our approach is highly competitive with respect to current planners that natively support the considered class of preferences.

Introduction

Planning with preferences, also called “over-subscription planning” in [2, 5?], concerns the generation of plans for problems involving soft goals or soft state-trajectory constraints (called preferences in PDDL3), that it is desired a plan satisfies, but that do not have to be satisfied. The quality of a solution plan for these problems depends on the soft goals and preferences that are satisfied.

For instance, a useful class of preferences than can be expressed in PDDL3 [6] consists of *always preferences*, requiring that a certain condition should hold in *every* state reached by a plan. As discussed in [? ? 6?], adding always preferences to the problem model can be very useful to express safety or maintenance conditions, and other desired plan properties. An simple example of such conditions is “whenever a building surveillance robot is outside a room, all the room doors should be closed”.

PDDL3 supports other useful types of preferences, and in particular the qualitative preferences of types *at-end*, which

are which are equivalent to soft goals, *sometime*, *sometime-before* and *at-most-once*, which are all the types used in the available benchmarks for planning with qualitative PDDL3 preferences [6]. Examples of preferences that can be expressed through these constructs in a logistics domain are: “sometime during the plan the fuel in the tank of every vehicle should be full”, “a certain depots should be visited before another once”, “every store should be visited at most once” (the reader can find additional examples in [6]).

In this paper, we study propositional planning with these types of preferences through a compilation approach.

Related Work

Our compilative approach is inspired by the work of Keyder and Geffner [?] on compiling soft goals into STRIPS with action costs (here denoted with STRIPS+). In this work the compilation scheme introduces, for each soft goal p of the problem, a dummy goal p' that can be achieved using two actions in mutual exclusion. The first one, which is called *collect*(p), has cost equal to 0 and requires that p be true when it is applied; the second one, which is called *forgo*(p), has cost equal to the utility of p and requires that p be false when it is applied.

Both of these action can be performed at the end of the plan and for each soft goal p but just one of $\{collect(p), forgo(p)\}$ can appear in the plan depending on whether the soft goal has been achieved or not. This scheme has achieved good performance which can be improved with the use of an ad hoc admissible heuristic based on the reachability of soft goals [9].

The most prominent existing planners supporting PDDL3 preferences are HPlan-P [? ?], which won the “qualitative preference” track of IPC-5, MIPS-XXL [? ?] and the more recent LPRPG-P [?] and its extension in [?]. These (forward) planners represent preferences through automata whose states are synchronised with the states generated by the action plans, so that an accepting automaton state corresponds to preference satisfaction. For the synchronisation, HPlan-P and LPRPG-P use planner-specific techniques, while MIPS-XXL compiles the automata by modifying the domain operators and adding new ones modelling the automata transitions of the grounded preferences.

Our computation method is very different from the one of MIPS-XXL since, rather than translating automata into new

operators, the problem preferences are compiled by only modifying the domain operators, possibly creating multiple variants of them. Moreover, our compiled files only use STRIPS+, while MIPS-XXL also uses numerical fluents.¹

The works on compiling LTL goal formulas by Cresswell and Coddington [?] and Rintanen [?] are also somewhat related to ours, but with important differences. Their methods handle *hard* temporally extended goals instead of preferences, i.e., every temporally extended goal must be satisfied in a valid plan, and hence there is no notion of plan quality referred to the amount of satisfied preferences. Rintanen's compilation considers only single literals in the always formulae (while we deal with arbitrary CNF formulas), and it appears that extending it to handle more general formulas requires substantial new techniques [?]. An implementation of the Crosswell and Coddington's approach is unavailable, but Bayer and McIlraith [?] observed that their approach suffers exponential blow up problems and performs less efficiently than the approach of HPlan-P.

IMPORTANTE, CONFRONTO LAVORO NEBEL: An important work about soft-trajectory constraints compilation, which is closely related to ours, has been recently proposed by Wright, Mattüller and Nebel in [?] (cerca riferimento articolo Nebel). This approach is based on the compilation of the soft trajectory constraints into conditional effects and state dependent action costs using LTL_f and Büchi automata. There are some similarities between our and their approach but at the same time there are also differences.

FP: differenze approccio Nebel e nostro: 1) numero di fluenti introdotto nella compilazione diverso; 2) il nostro è un approccio più specifico PDDL3-oriented, il loro più generale; 3) diverso meccanismo di aggiornamento dei costi, nel loro caso ricompensa e penalità, nel nostro solo penalità; 4) il loro schema prevede quindi costi negativi e positivi, il nostro positivi; nel loro caso per avere solo costi positivi è necessario perdere l'ottimalità nel nostro caso no ed inoltre volendo potremmo introdurre dei costi negativi per quelle preferenze la cui violazione può essere testata solo alla fine del piano mantenendo l'ottimalità; ho fatto inoltre menzione del fatto che i costi possono essere incrementanti il prima possibile (es. always)

1) In our approach, given a preference P , we introduce at most a pair of boolean fluents, typically one additional fluent to represent if a preference is violated or not (P -violated) and in some cases an additional fluent to correctly represent the status of a preference during the planning, while in their approach it is introduced a boolean variable for each state of the corresponding automaton of P . 2) Their approach is more general while ours is focused on PDDL3 constraints and therefore it is more specific.

3) In their work the cost of the plan during the planning is updated by using rewards and penalties (negative and positive costs respectively). The cost of the plan is increased

¹Another compilation scheme using numerical fluents is considered in [6] to study the expressiveness of PDDL3 (without an implementation).

whenever a violation of a preference (also reversible) occurs. On the contrary, if an operator causes the satisfaction of a preference then the cost of the plan is decreased. In both cases the negative or positive cost is equal to the utility of the interested preference². 4) This type of cost update requires the use of negative costs while our compilation scheme produces a problem whose costs are monotonically increasing because, similarly to what was proposed in Keyder and Geffner, costs are realized only at the end of the planning. In our scheme some costs can be anticipated for those preferences whose violation is irreversible (e.g. always, sometime-before) and negative costs could be used for those preferences that may be "temporarily" violated (e.g. sometime, at-end). In both cases our scheme would maintain the optimality but in this work we have provided a compilation based only on positive costs in order to take advantage of a wider spectrum of classical planners (few planners still support negative costs).

We propose a compilation scheme for translating a STRIPS problem with PDDL3 qualitative preferences into an equivalent STRIPS+ problem. Handling action costs is a practically important, basic functionality that is supported by many powerful planners; the proposed compilation method allows them to immediately support (through the compiled problems) the considered class of preferences with no change to their algorithms and code.

Propositional Planning with Qualitative PDDL3 Preferences

Operator-Preference Interactions

Compilation of Qualitative Preferences

Experimental Results

Experiments Description

We implemented the proposed compilation scheme and have evaluated it by two sets of experiments with different purposes. On the one hand we evaluated the scheme in a satisficing planning context in which we focused on the search for sub-optimal plans using different planning systems, while in the other we focus on the search of optimal plans using admissible heuristics.

Regarding the comparison in the context of the satisficing planning we have considered the following STRIPS+ planning system LAMA[10], Mercury [7], MIPlan [8], IBaCoP2 [3], which are some of the best performing planning system in IPC8 [11], and Fast Downward Stone Soup 2018[?], fdremixcomplete [?] (abbreviated with fdremix), which are some of the best performing planning system in the last IPC9 [1] which have been compared with

²Messo in footnote altrimenti era troppo lungo: Note that both the violation and the satisfaction of a preference may be temporary conditions depending on the type of interested preference. For example an always preference can be irreversibly violated and its satisfaction can only be evaluated at the end of the plan considering the whole trajectory of the states; on the contrary a sometime-after preference can be satisfied and violated several times during the execution of the plan.

LPRPG-P [4], which is one of the performing planner which supports PDDL3 preferences. Moreover have considered our specifically enhanced version of LAMA for planning with soft goal, which is $LAMA_P(h_R)$, which makes use of admissible heuristic h_R to test the reachability of the soft goals of the problem [9].

As benchmark we have considered the five domains of the qualitative preference track of IPC5 [6] which involve always, sometime, sometime-before, at-most-once and soft goal preferences, i.e Rovers, TPP, Trucks, Openstacks and Storage.

For each original problem all preferences and each original utility were kept. The the classical planners were runned on the compiled problems while LPRPG-P was runned on the original problems of the competition. All the experiments were conducted on a 2.00GHz Core Intel(R) Xeon(R) CPU E5-2620 machine with CPU-time and memory limits of 30 minutes and 8GiB, respectively, for each run of every tested planner. We have tested 8 planners for 5 domains each of which consists of 20 instances for a total of 800 runs.

Table 1 shows the performances of the considered planning system in term of plans quality. As quality measure we have used the IPC quality score, a popular metric of which we have reported a brief description [?].

Given a planner p and a task i we assign, if p solves i , the following score to p :

$$score(p, i) = \frac{cost_{best}(i)}{cost(p, i)}$$

where $cost_{best}(i)$ is the cost of the best know solution for the task i found by any planner, and $cost(p, i)$ is the cost of the solution found by the considered planner p in 30 minutes. In our case our reference for $cost_{best}(i)$ is equal to the cost of the best solution among the tested planners within 30 minutes. If p did not find a solution within the time assigned, then $score(p, i)$ is equal to 0 in order to reward both quality and coverage.

The quality score assigned to each tested planner p is set equal to sum of the quality scores assigned to p over all the considered instances:

$$score(p) = \sum_{i \in tasks} score(p, i)$$

Table 1 reports the quality comparison using the IPC score described above. It is splitted into six parts, at top we have reported the qualitative comparison considering all kinds of preferences together in the computation of the IPC score, while in the remaining subtables we have splitted the have considered each considered class of preference separately (which is indicated in the header of each subtable).

NOTA (FP): selezionare un numero di pianificatori significativi da includere nella tabella per alleggerire la tabella.

Figures 1—?? show the qualitative comparison in a more detailed way. In these histograms we have reported, for each instance of each domain, another quality measure, which we have denoted with α_{cost} . Each figure is associated with one of the considered domains.

In particular we have evaluated the best performing planners according to the results showed in Table 1 which are $LAMA_P(h_R)$ and LPRPG-P respectively.

We reported a brief description of the metric α_{cost} that we used. Given a planner p and a task i we assign, if p solves i , the following score to p :

$$\alpha_{cost}(p, i) = cost(p, i) / cost_{total}(i) = \frac{\sum_{P \in \mathcal{P}(i) : \pi \neq P} c(P)}{\sum_{P \in \mathcal{P}(i)} c(P)}$$

where $cost(p, i)$ is the cost of the solution found by planner p for the task i within 30 minutes and $cost_{total}(i)$ is the sum of the costs of all the preferences involved in the task i (note that $\mathcal{P}(i)$ denote the set of the preferences of the task i).

From the previous definition, $\alpha_{cost}(p, i)$ could vary between 0 and 1. If $\alpha_{cost}(p, i) = 0$, then it means that the numerator $cost(p, i)$ is equal to 0 and that p has found an optimal plan for i which satisfies all the preferences of the problem. On the contrary, if $\alpha_{cost}(p, i) = 1$, then it means that p has found the worst plan for i where all the preferences of the problem are violated.

More generally given an instance i , the ratio $\alpha_{cost}(p, i)$, comparing plans produced by different systems, tell us which planner has achieved the satisfaction of the most useful subset of preferences in absolute terms. In particular, the planner with the lowest ratio is the planner who got the best performance on that particular instance.

Satisficing Planning Results

The results obtained comparing the planners considered above show that the compilative approach is almost always preferable since the classical planners obtain an higher IPC score than LPRPG-P except for Mercury and MIPlan.

In Table 1 we have included, for the lack of space, just the more significant planning systems which are $LAMA_P(h_R)$, FDRemix, LPRPG-P and Mercury. We have chosen these because $LAMA_P(h_R)$ and FDRemix realize the best performance in term of IPC score among those considered classical planners while Mercury the worst.

With reference to Table 1 the compilative approach seems at glance to be particularly preferable in Rovers, Trucks and Storage. In these domains each classical planner performs better or at least comparable than LPRPG-P (except for Mercury in Trucks); IBaCoP2 performs particularly well in Rovers while FDRemix in Trucks. Also MIPlan get a well performance in Trucks but is penalized due to coverage (it solves only 15 instances out of 20). The planning system from the more recent IPC9 FDRemix and Fast Downward Stone Soup 2018 performs better in this benchmark than the planning system from IPC8 but the enhanced version $LAMA_P(h_R)$ is better than everyone else indeed it improves the performance of LAMA in all the considered domains except in Rovers where there is no soft goal.

In Figure ?? we can see

In TPP the compilative approach seems to be very ineffective, each classical planner achieves an extremely lower quality performance compared to LPRPG-P. The bad performances in this domain are probably due to the many soft goals and sometime preferences because, as shown in [9], the compilation of soft goals can be sometime problematic and neither the use of the reachability heuristic h_R in $LAMA_P(h_R)$ can compensate this weakness.

Indeed the part of Table 1, which concerns soft goals, clearly shows that LPRPG-P is overall more performing than the classical planners especially in TPP in term of satisfied soft goal and sometime preferences. This aspect is clearly observable Figures 2a and 2b where we can see that the compilative approach fails to achieve the percentage of satisfied soft goal and sometime preferences achieved by LPRPG-P starting from instance #4 and instance #11 for soft an sometime preferences respectively. Looking at 1 we can observe that $LAMA_P(h_R)$ achieves a better satisfaction of always, sometime-before and at-most-once preferences compared to LPRPG-P, but at the expense soft-goal and sometime preferences which are clearly more expensive to violate (and so more useful to satisfy).

Looking at Figure 1b, where we have reported the α_{cost} comparison between $LAMA_P(h_R)$ and LPRPG-P considering all kind of preferences, we can observe that the classical planner achieves a better, worst and equal performance in 10, 9 and 1 instances out of 20.

Regarding Opentacks the tested planners achieve a comparable performance even if the classical planners are slightly penalized compared to LPRPG-P. Also in this case the classical planners have difficulty to satisfy soft goal as shown in Table 1.

Looking at Figure 1a we can observe that LAMA and fdremix generally compute higher quality plans than LPRPG-P in Rovers, in particular they find better plan in 15 and 16 instances out of 20 respectively. Looking at Figure 1b we can observe that LAMA and fdremix compute lower quality plans than LPRPG-P for more than half of the instances. Both classical system work better than LPRPGP in smaller instances but they get worse as the size increases. Looking at Figure 1c we can say that LAMA and fdremix performs better for more than half of the instances, in particular they find better plan in 13 and 16 instances out of 20. Note that the classical planners get the optimal solution for some of the first seven instances. Looking at Figure 1d we can say that both approaches achieve a comparable performance even if LPRPG-P generally finds slightly better solutions than both classical competitors in 13 instances out of 20.

Optimal Planning Results

Similarly to what has been done in [12], we have tested our scheme using some admissible heuristics which are h^{blind} , h^{max} and $h^{M\&S}$ which guarantee us the optimality of the solution found. Starting from the IPC5 domains, we generated simpler instances by randomly sampling subsets of the soft trajectory constraints. Starting from each instance we have generated five new instances with 1%, 5%, 10%, 20% and 40% of the (grounded) soft trajectory constraints while the hard goals have remained unchanged.

Since we do not have the instances that have been used in the aforementioned paper, we have generated, for each percentage of sampling preferences (except for 100 %), five sampled instances in order to average the obtained results. The results about this experiment are shown Table 2. The results inherent to Openstacks have been excluded because it was not possible to find optimal plans even for the simplest instances.
